the regulation of trans made up of four core h primary building block	omatin structure plays an important role in cription in eukaryotes. The nucleosome, istone proteins (H2A, H2B, H3 and H4), is the s of chromatin. The N-terminal tail of core fferent posttranslational modifications	

including acetylation, phosphorylation and methylation. These modifications occur in response to cell signal stimuli and have a direct effect on gene expression. In most species, the histone H2B is primarily acetylated at lysines 5, 12, 15 and 20. Histone H3 is primarily acetylated at lysines 9, 14, 18 and 23. Acetylation at lysine 9 appears to have a dominant role in histone deposition and chromatin assembly in some organisms. Phosphorylation at Ser10 of histone H3 is tightly correlated with chromosome condensation during both mitosis and meiosis.
