## **IR-beta Antibody Blocking Peptide**

Catalog Number:	bs-0290P
Activity:	Not tested
Purification:	HPLC
Storage:	Shipped at 4°C. Stored at -20°C for one year. Avoid repeated freeze/thaw cycles.
Background:	The human insulin receptor is a heterotetrameric membrane glycoprotein consisting of
	disulfide linked subunits in a beta-alpha-alpha-beta configuration. The beta subunit (95
	kDa) possesses a single transmembrane domain, whereas the alpha subunit (135 kDa) is
	completely extracellular. The insulin receptor exhibits receptor tyrosine kinase (RTK)
	activity. RTKs are single pass transmembrane receptors that possess intrinsic cytoplasmic
	enzymatic activity, catalyzing the transfer of the gamma phosphate of ATP to tyrosine
	residues in protein substrates. RTKs are essential components of signal transduction
	pathways that affect cell proliferation, differentiation, migration and metabolism.
	Included in this large protein family are the insulin receptor and the receptors for growth
	factors such as epidermal growth factor, fibroblast growth factor and vascular endothelial
	growth factor. Receptor activation occurs through ligand binding, which facilitates receptor
	dimerization and autophosphorylation of specific tyrosine residues in the cytoplasmic
	portion. The interaction of insulin with the alpha subunit of the insulin receptor activates
	the protein tyrosine kinase of the beta subunit, which then undergoes an
	autophosphorylation that increases its tyrosine kinase activity. Three adapter proteins,
	IRS1, IRS2 and Shc, become phosphorylated on tyrosine residues following insulin receptor
	activation. These three phosphorylated proteins then interact with SH2 domain containing
	signaling proteins.
