Background:	The WNT gene family consists of structurally related genes which encode secreted signaling
	proteins. These proteins have been implicated in oncogenesis and in several developmental
	processes, including regulation of cell fate and patterning during embryogenesis. This gene
	encodes a member of the WNT family that signals through both the canonical and non-
	canonical WNT pathways. This protein is a ligand for the seven transmembrane receptor
	frizzled-5 and the tyrosine kinase orphan receptor 2. This protein plays an essential role in
	regulating developmental pathways during embryogenesis. This protein may also play a
	role in oncogenesis. Mutations in this gene are the cause of autosomal dominant Robinow
	syndrome. Alternate splicing results in multiple transcript variants. [provided by RefSeq, Jan
